Programming Paradigms

Lecture 6: Control Flow (Part 1)

Prof. Dr. Michael Pradel

Software Lab, University of Stuttgart

Winter 2019/2020

Wake-up Exercise

What does the following Java code print?

```
class Warmup {
    static void f(int a, int b) {
        System.out.println(a + ", " + b);
    }

    public static void main(String[] args) {
        int i = 5;
        f(i++, --i);
    }
}
```

https://ilias3.uni-stuttgart.de/vote/0ZT9

Wake-up Exercise

What does the following Java code print?

```
class Warmup {
    static void f(int a, int b) {
        System.out.println(a + ", " + b);
    }

    public static void main(String[] args) {
        int i = 5;
        f(i++, --i);
    }
}
```

Result: 5, 5

https://ilias3.uni-stuttgart.de/vote/0ZT9

Wake-up Exercise

What does the following Java code print?

```
class Warmup {
    static void f(int a, int b) {
        System.out.println(a + ", " + b);
    }

    public static void main(String[] args) {
        int i = 5;
        f(i++, --i);
    }
}
```

Post-increment: Returns `i` and then increments it

Result: 5, 5

https://ilias3.uni-stuttgart.de/vote/0ZT9

Wake-up Exercise

What does the following Java code print?

```
class Warmup {
    static void f(int a, int b) {
        System.out.println(a + ", " + b);
    }

    public static void main(String[] args) {
        int i = 5;
        f(i++, --i);
    }
}
```

Pre-decrement: Decrements `i` and then returns it

Result: 5, 5

https://ilias3.uni-stuttgart.de/vote/0ZT9

Wake-up Exercise

What does the following Java code print?

```
class Warmup {
    static void f(int a, int b) {
        System.out.println(a + ", " + b);
    }

    public static void main(String[] args) {
        int i = 5;
        f(i++, --i);
    }
}
```

Evaluation order:

Left-to-right

Result: 5, 5

https://ilias3.uni-stuttgart.de/vote/0ZT9

Control Flow

Control flow: Ordering of instructions

- Fundamental to most models of computation
- Common language mechanisms
  - Sequencing, selection, iteration, recursion, concurrency, exceptions
- Each PL defines its rules
  - Think in terms of concepts, not specific syntax

Overview

- Expression Evaluation
- Structured and Unstructured Control Flow
- Selection
- Iteration
- Recursion

Expressions

Operator vs. operand

- Operator: Built-in function with a simple syntax
- Operand: Arguments of operator
- Examples:

```
i++

foo() + 23

(a * b) / c
```

Expressions: Notation

Three popular notations

- Prefix
  - `op a b` or `op(a, b)` or `(op a b)`
- Infix
  - `a op b`
- Postfix
  - `a b op`

Expressions: Notation

Three popular notations

- Prefix
  - `op a b` or `op(a, b)` or `(op a b)`

Example: Lisp

`(* (+ 1 3) 2)`

- Infix
  - `a op b`
- Postfix
  - `a b op`

Expressions: Notation

Three popular notations

- Prefix
  - `op a b` or `op(a, b)` or `(op a b)`
- Infix
  - `a op b` —— **Example: Java**

    `(1 + 3) * 2`
- Postfix
  - `a b op`

Expressions: Notation

Three popular notations

- Prefix
  - `op a b` or `op(a, b)` or `(op a b)`
- Infix
  - `a op b`
- Postfix
  - `a b op`

Example: C

`a++`

Multiplicity

Number of arguments expected by an operator

- Unary
  - `a++` or `!cond`
- Binary
  - `a + b` or `x instanceof MyClass`
- Ternary
  - `cond ?  a :  b`
- (More are possible, but uncommon in practice)

Order of Evaluating Expressions

Given a complex expression, in what order to evaluate it?

Examples:

- Multiple arithmetic operations in Python:

  `2 + 3 * 4`

- Mix of boolean and other expressions in Java:

  `!x && a == false`

- Dereference and increment a pointer in C:

  `*p++`

Precedence and Associativity

Choice among evaluation orders:

Specified by precendence and associativity rules of the PL

- Precedence: Specify which operators group “more tighly” than others
- Associativity: For operators of equal precedence, specify whether to group to the left or right

Precedence Levels in C

<table>
<tr><th>Operator</th><th>Meaning</th></tr>
<tr><td>++, --</td><td>Post-increment, post-decrement</td></tr>
<tr><td>++, --
*</td><td>Pre-increment, pre-decrement
Pointer dereference</td></tr>
<tr><td><, ></td><td>Inequality test</td></tr>
<tr><td>==, !=</td><td>Equality test</td></tr>
<tr><td>&&</td><td>Logical and</td></tr>
<tr><td>||</td><td>Logical or</td></tr>
<tr><td>=, +=</td><td>Assignment</td></tr>
</table>

Higher means higher precedence

This list is incomplete.

Precedence Levels in C

Operator	Meaning
++, --	Post-increment, post-decrement
++, --	Pre-increment, pre-decrement
*	Pointer dereference
<, >	Inequality test
==, !=	Equality test
&&	Logical and
||	Logical or
=, +=	Assignment

Same precedence level

This list is incomplete.

Examples

- **Dereference and increment a pointer:**
  - `*p++`
- **Mix of logical operators:**
  - `a && b || c`
- **Mix of inequality and equality tests:**
  - `x < y == foo`

Examples

- **Dereference and increment a pointer:**
  - `*p++` means `*(p++)`
- **Mix of logical operators:**
  - `a && b || c` means `(a && b) || c`
- **Mix of inequality and equality tests:**
  - `x < y == foo` means `(x < y) == foo`

Examples

- **Dereference and increment a pointer:**
  - `*p++` means `*(p++)`
- **Mix of logical operators:**
  - `a && b || c` means `(a && b) || c`
- **Mix of inequality and equality tests:**
  - `x < y == foo` means `(x < y) == foo`

General rule:

When in doubt, use parentheses

Associativity Rules

- Decide about same-level operators
- Arithmetic operators:

  Mostly left-to-right a.k.a. left-associative

  - `12 - 3 - 2` yields `7` in most languages
  - Exception: Exponentiation is mostly right-associative
    - `2 ** 3 ** 2` yields `512` in most languages
    - But: `2 ^^ 3 ^^ 2` yields `64` in Excel
- Assignments: Mostly right-associative
  - `a = b = a + c` assigns `a + c` into `b` and then `a`

Quiz: Precedence and Associativity

1) What are the values of `foo` and `bar`

   (a) when assignments are left-associative?

   (b) when assignments are right-associative?

```
int foo = 1, bar = 2;
foo = bar = foo + bar;
```

2) What is the value of `z`

   (a) when `&&` has higher prededence than `||`?

   (b) when `||` has higher prededence than `&&`?

```
bool x = false, y = false, z = true;
bool z = x || y && y || z;
```

https://ilias3.uni-stuttgart.de/vote/0ZT9

Quiz: Precedence and Associativity

1) What are the values of `foo` and `bar`

foo=2, bar=4

  (a) when assignments are left-associative?
  (b) when assignments are right-associative?

foo=3, bar=3

```
int foo = 1, bar = 2;
foo = bar = foo + bar;
```

2) What is the value of `z`

true

  (a) when `&&` has higher prededence than `||`?
  (b) when `||` has higher prededence than `&&`?

false

```
bool x = false, y = false, z = true;
bool z = x || y && y || z;
```

https://ilias3.uni-stuttgart.de/vote/0ZT9

Ordering within Expressions

- **Discussed so far:**
  Order of performing operations
- **But: In what order are the operands evaluated?**
- **Example:**
  `a - f(b) - c * d`

Ordering within Expressions

- **Discussed so far:**
  Order of performing operations
- **But: In what order are the operands evaluated?**
- **Example:**
  `a - f(b) - c * d`

  $\boxed{\texttt{c * d}}$

  Has precedence over subtraction

Ordering within Expressions

- **Discussed so far:**
  Order of performing operations
- **But: In what order are the operands evaluated?**
- **Example:**

```
a - f(b) - c * d
```

Subtraction is left-associative:
This is computed first

Ordering within Expressions

- **Discussed so far:**
  Order of performing operations
- **But: In what order are the operands evaluated?**
- **Example:**

```
a - f(b) - c * d
```

But: Which of these two operands is evaluated first?

Why Does It Matter?

- **Reason 1: Side effects**
  - Evaluating `f(b)` may modify `c` or `d`
- **Reason 2: Compiler optimizations**
  - Influences register allocation and instruction scheduling

Example:

```
a - f(b) - c * d
```

Ordering: Language-specific

Different PLs: Different ordering within expressions

- Java and C#: Left-to-right
- C and many other languages: Undefined
  - Compiler can choose best order
  - Earlier example again:

```
int i = 5;
f(i++, --i);
```

Ordering: Language-specific

Different PLs: Different ordering within expressions

- Java and C#: Left-to-right
- C and many other languages: Undefined
  - Compiler can choose best order
  - Earlier example again:

```
int i = 5;
f(i++, --i);
```

May pass 5, 5 (left-to-right) or 4, 4 (right-to-left) to `f`

Short-circuit Evaluation

- **Saving time** when evaluating **boolean expressions**
- **Example:**

```
if (very_unlikely && very_expensive())
{
      ...
}
```

Short-circuit Evaluation

- **Saving time** when evaluating **boolean expressions**
- **Example:**

```
if (very_unlikely && very_expensive())
{
      ...
}
```

If first operand is false, no need to evaluate the second

Short-circuit Evaluation

- **Saving time** **when evaluating** **boolean expressions**
- **Example:**

```
if (very_unlikely && very_expensive())
{
    ...
}
```

But: Side effects of second operand may or may not happen

Short-circuit Evaluation (2)

- **Most PLs implement short-circuit evaluation**
  - Boolean and: Ignore second operand if first is false
  - Boolean or: Ignore second operand if first is true
- **One (relatively) popular exception: Pascal**

Short-circuit Evaluation (3)

- Beware that side effects in some boolean expressions may not happen
- Use it to your advantage:

```
// C code
p = my_list;
while (p && p->key != val) {
    ...
    p = p ->next;
}
```

Overview

- Expression Evaluation
- Structured and Unstructured Control Flow
- Selection
- Iteration
- Recursion

Control Flow with `goto`s

- **Most assembly languages: Control flow via conditional and unconditional jumps**
- **Early PLs: `goto` statements**
  - Jump to a statement label
  - Target label can be anywhere in the code

Example

```c
// C code
int a = 10;
my_label: do {
    if(a == 12) {
        a = a + 1;
        goto my_label;
    }
    printf("%d\n", a);
    a++;
} while(a < 15);
```

Example

```
// C code
int a = 10;
my_label: do {
    if(a == 12) {
        a = a + 1;
        goto my_label;
    }
    printf("%d\n", a);
    a++;
} while(a < 15);
```

Output:

10

11

13

14

Quiz: Goto Hell

```c
// C code
int result = 0;
int number = 3;
one : for (int i = 0; i < number; ++i)
{
three:
    result += i;
    goto two;
}
goto one;
two : if (result < 2)
{
    goto three;
}
printf("%d\n", result);
```

What does this code print?

Quiz: Goto Hell

```
// C code
int result = 0;
int number = 3;
one : for (int i = 0; i < number; ++i)
{
three:
    result += i;
    goto two;
}
goto one;
two : if (result < 2)
{
    goto three;
}
printf("%d\n", result);
```

What does this code print?

Nothing! It never terminates.

Beyond `gotos`

- ***Go To Statement Considered Harmful*** **article by Edsger Dijkstra (CACM, 1968)**
- **Instead: Structured control flow**
- **Express algorithms with**
  - Sequencing
  - Selection
  - Iteration

Avoiding `goto`s

Use case of `goto`

- Jump to end of subroutine
- Escape from middle of loop
- Propagate to surrounding context

Structured control flow alternative

- `return` statement
- `break` and `continue` statements
- Exceptions

Continuations

- **Generalization of `gotos`**
- **Powerful language feature:**
  Allows programmer to define new control flow constructs
  - Exceptions
  - Iterators
  - Coroutines
  - etc.

Continuations (2)

- **High-level definition: Context in which to continue execution**
- **Low-level definition: Three parts**
  - Code address (where to continue)
  - Referencing environment (for resolving names)
  - Another continuation (to use when code returns)

Example

```
# Ruby code
def foo(i ,c)
    printf("start %d; ", i)
    if i < 3
        foo(i+1, c)
    else c.call(i)
    end
    printf "end %d; ", i
end

v = callcc{ |d| foo(1, d) }
printf "got %d\n", v
```

Example

```
# Ruby code
def foo(i ,c)
    printf("start %d; ", i)
    if i < 3
        foo(i+1, c)
    else c.call(i)
    end
    printf "end %d; ", i
end
```

Creates a continuation, i.e., execution will continue here

```
v = callcc{ |d| foo(1, d) }
printf "got %d\n", v
```

Example

```
# Ruby code
def foo(i ,c)
    printf("start %d; ", i)
    if i < 3
        foo(i+1, c)
    else c.call(i)
    end
    printf "end %d; ", i
end
```

`d` is a reference to the continuation

```
v = callcc{ |d| foo(1, d) }
printf "got %d\n", v
```

Example

```ruby
# Ruby code
def foo(i ,c)
    printf("start %d; ", i)
    if i < 3
        foo(i+1, c)
    else c.call(i)
    end
    printf "end %d; ", i
end

v = callcc{ |d| foo(1, d) }
printf "got %d\n", v
```

`foo` gets called and calls itself two more times

Example

```
# Ruby code
def foo(i ,c)
    printf("start %d; ", i)
    if i < 3
        foo(i+1, c)
    else c.call(i)
    end
    printf "end %d; ", i
end

v = callcc{ |d| foo(1, d) }
printf "got %d\n", v
```

Jumps into context captured by `c` and makes `callcc` appear to return `i`

Example

```
# Ruby code
def foo(i ,c)
    printf("start %d; ", i)
    if i < 3
        foo(i+1, c)
    else c.call(i)
    end
    printf "end %d; ", i
end
```

Code prints:

start 1; start 2; start 3; got 3

```
v = callcc{ |d| foo(1, d) }
printf "got %d\n", v
```

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

`bar` gets called and calls itself two more times

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

Creates a continuation, when gets stored in c

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

n is 2, therefore execution jumps to the continuation

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

We are here again!

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1  ←  We are here again!
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

`n` is 1, therefore execution jumps to the continuation

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

n is 0. We are finally done

Another Example

```
def here
    return callcc { |a| return a }
end

def bar(i)
    printf "start %d; ", i
    b = if i < 3 then bar(i+1) else here end
    printf "end %d; ", i
    return b
end

n = 3
c = bar(1)
n = n - 1
puts  # print newline
if n > 0 then c.call(c) end
puts "done"
```

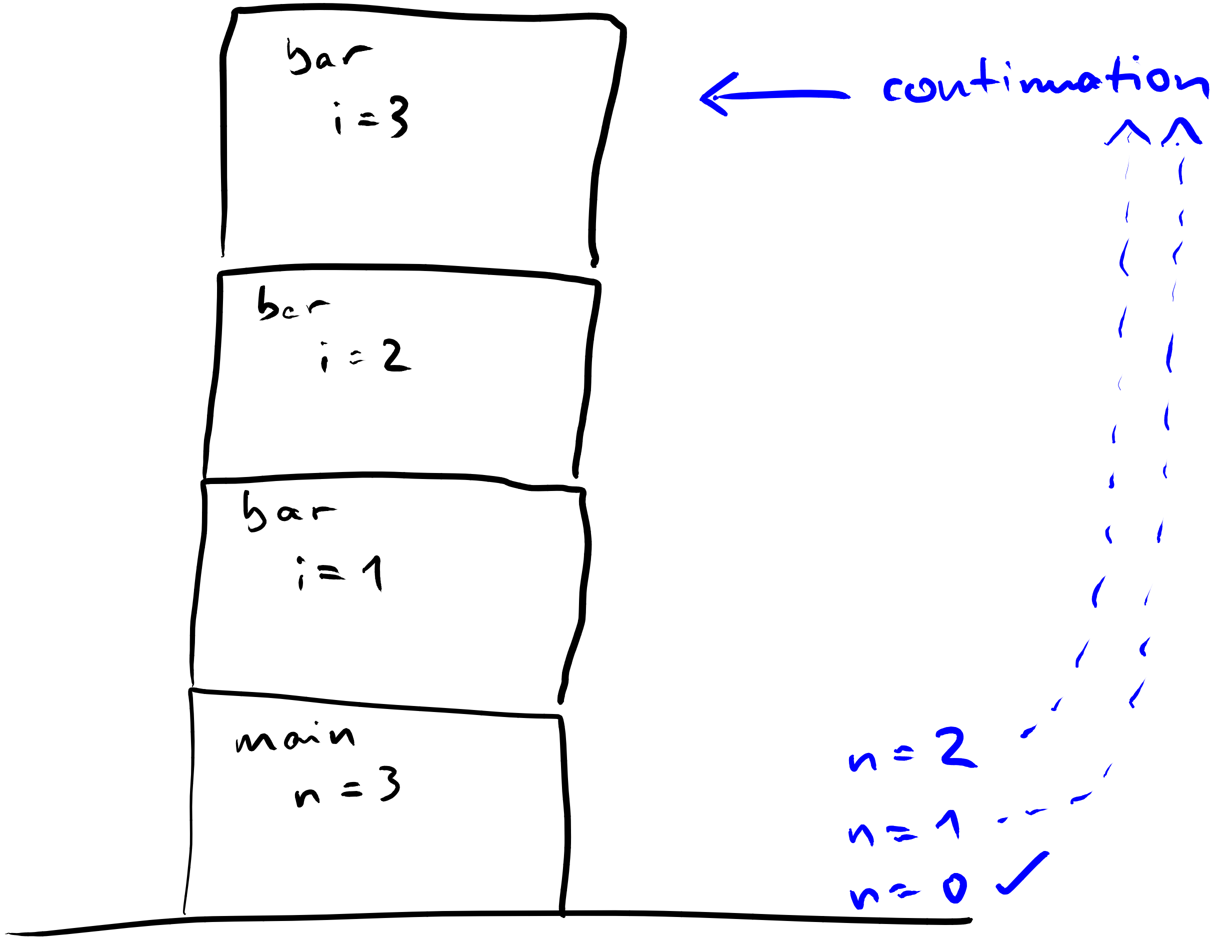
Code prints:

start 1; start 2; start 3; end 3; end 2; end 1;

end 3; end 2; end 1;

end 3; end 2; end 1;

done



bar
i = 3
bar
i = 2
bar
i = 1
main
n = 3
continuation
n = 2
n = 1
n = 0 ✓
